1 General

1.1 Introduction

vlink is a portable linker which can be configured to support multiple input and output file formats at once. It even allows to link input files with a different format in a single run and generate the output file format of your choice from it.

The linker supports linking with objects, object archives (static libraries) and shared objects or libraries. It can generate an executable file with or without additional information for dynamic linking, a shared object, or a new object suitable for another linker pass.

Empty sections and other unused data are deleted to achieve a size-optimized output.

1.2 Legal

vlink is copyright 1995-2020 by Frank Wille.

This archive may be redistributed without modifications and used for non-commercial purposes.

An exception for commercial usage is granted, provided that the target OS is AmigaOS/68k.

Resulting binaries may be distributed commercially without further licensing.

In all other cases you need my written consent.

1.3 Installation

vlink comes as a stand-alone program, so no further installation is necessary. To use vlink with vbcc, copy the binary to vbcc/bin, following the installation instructions for vbcc.
2 The Linker

2.1 Usage

vlink links the object and archive files given on the command line into a new object file. The output object file is either an executable program, a shared object suitable for loading at run-time, or an object file that can once again be processed by vlink.

Object files and archives are processed in the order given on the command line. Unlike other linkers you usually have to specify each library to link against only once, as vlink is smart enough to figure out all dependencies.

The file format of an input object file is determined automatically by the linker. The default output file format is compiled in (see -v) and may be changed by -b. Optionally, the default library search path can also be compiled in and is visible with -v as well.

The number of output file formats included is configurable at compile time.

2.2 Supported file formats

The following file formats are supported:

a.out Currently supported:
- aoutnull (Default with standard relocs and undefined endianess)
- aoutbsd68k (NetBSD/68k)
- aoutbsd68k4k (NetBSD/68k 4K page size)
- aoutsun010 (SunOS 68010 and AmigaOS/Atari 68000/010)
- aoutsun020 (SunOS 68020 and AmigaOS/Atari 68020-68060)
- aoutbsdi386 (NetBSD/i386)
- aoutpc386
- aoutmint (Embeds a.out in TOS format for Atari MiNT executables)
- aoutjaguar (M68k with special, word-swapped RISC relocations)

Small data offset: 0x8000 (unused). Linker symbols: __GLOBAL_OFFSET_TABLE__, __PROCEDURE_LINKAGE_TABLE__, __DYNAMIC.

amigahunk
The AmigaDos hunk format for M68k. Requires AmigaOS 2.04 with -Rshort. No shared objects. Small data offset 0x7ffe. Linker symbols:
- DATA_BAS_ (PhxAss)
- DATA_LEN_ (PhxAss)
- BSS_LEN_ (PhxAss)
- LinkerDB
- BSSBAS (SASC/StormC)
- BSSLEN (SASC/StormC)
- ctors (SASC/StormC)
- dtors (SASC/StormC)
- (_RESLEN (SASC)
- (_RESBASE (SASC)
- (NEWDATAL (SASC)
- (__DATA_BAS (DICE-C)
- (__DATA_LEN (DICE-C)
- (__BSS_LEN (DICE-C)
- (__RESIDENT (DICE-C)
- (__machtype (GNU-gcc)
- (__text_size (GNU-gcc)
- (__data_size (GNU-gcc)
- (__bss_size (GNU-gcc)

Automatic constructor/destructor function tables: ___ctors and ___dtors (will be mapped automatically to __CTOR_LIST__ and __DTOR_LIST__).

Referencing _RESLEN switches the hunk-format output module into Resident mode, which will append a special relocation table to the initialized part of the data-bss section and warns about absolute references from other sections. This mode can be used to create reentrant, "pure" programs, for use with the AmigaOS resident command.

Supports -Rstd and -Rshort. -hunkattr can be used to overwrite the memory flags of an input section. This format was called "amigaos" in former vlink versions.

amigaehf An extension of the AmigaDOS hunk format for the PowerPC, 32-bit, big endian, as introduced by Haage&Partner GmbH for WarpOS. No executables (they are in amigahunk format) or shared objects. The same linker symbols, constructors/destructors as under amigahunk are supported. Additionally, @_name symbols will be created on demand (when referenced). Supports -Rstd, -Rshort and -hunkattr.

amsdos Absolute raw binary output, similar to rawbin2, but with a header for Amstrad/Schneider CPC computers.

ataritos Atari-ST TOS file format. Executables only at the moment. Symbol table in extended DRI format. Symbols may be section- or start-based (option -tos-textbased). The internal linker script defines _LinkerDB for small data and supports vbcc-style constructor/destructor tables in the data section (__CTOR_LIST__ and __DTOR_LIST__).

cbmprg Absolute raw binary output, similar to rawbin2, but with a header for Commodore 8-bit computers (PET, VIC-20, 64, etc.).

elf32amigaos Identical to elf32ppcbe, but when doing dynamic linking it requires that also all references from shared objects are resolved at link time. This is due to a limitation of the AmigaOS4 dynamic link editor (elf.library).

elf32arm ELF (executable linkable format) for the ARM architecture. 32-bit, little endian. Small data offset: 0x1000. Linker Symbols: __SDA_BASE__. Automatic
constructor/destructor function tables will be placed into the sections `.ctors` and `.dtors`. Supports `-Rstd` and `-Radd`.

**elf32aros**

ELF i386 32-bit little endian like elf32i386, but generates relocatable object files as executables. This format is used for the AROS (Amiga Research OS) operating system. Supports `-Rstd` and `-Radd`.

**elf32i386**

ELF (executable linkable format) for Intel 386 and better, 32-bit, little endian. No small data. Automatic constructor/destructor function tables will be placed into the sections `.ctors` and `.dtors`. Supports `-Rstd` and `-Radd`.

**elf32jag**

ELF (executable linkable format) for Atari Jaguar RISC, 32-bit, big endian. Small data offset: 0. Linker symbols: `_SDA_BASE_`. Automatic constructor/destructor function tables will be placed into the sections `.ctors` and `.dtors`. Supports `-Rstd` and `-Radd`.

**elf32m68k**

ELF (executable linkable format) for Motorola M68k, 32-bit, big endian. Small data offset: 0x8000. Linker symbols: `_SDA_BASE_`. Automatic constructor/destructor function tables will be placed into the sections `.ctors` and `.dtors`. Supports `-Rstd` and `-Radd`.

**elf32morphos**

Nearly identical to elf32powerup. Only difference is that `.sdata` and `.sbss` sections will not be merged as the MorphOS loader will take care of it. This format is used for MorphOS.

**elf32powerup**

ELF PowerPC 32-bit big endian like elf32ppcbe, but generates relocatable object files as executables. This format is used for the PowerUp kernel. The linker symbol `_LinkerDB` is defined for vbccppc-compatibility. Small data offset: 0x8000. This format was also called elf32amiga in former vlink versions.

**elf32ppcbe**

ELF (executable linkable format) for PowerPC, 32-bit, big endian. Small data offset: 0x8000. Linker symbols: `_SDA_BASE_` and `_SDA2_BASE_` (EABI only). Automatic constructor/destructor function tables will be placed into the sections `.ctors` and `.dtors`.

**elf64x86**

ELF (executable linkable format) for the x86_64 architecture. 64-bit, little endian. No small data. Automatic constructor/destructor function tables will be placed into the sections `.ctors` and `.dtors`. Supports `-Rstd` and `-Radd`.

**ihex**

Intel Hex format. No symbols. Output format only. Without a linker script, the raw binary will be relocated to base address 0.

**jagsrv**

Absolute raw binary output, similar to rawbin1, but with a header to make it load and execute via the Atari Jaguar SkunkBoard or the VirtualJaguar emulator.
rawbin1 Absolute raw binary file. The sections and base addresses have to be specified by a linker script (option -T). Gaps between sections are filled with 0-bytes. Without a linker script, the raw binary will be relocated to base address 0.

rawbin2 Similar to rawbin1. The only difference is that a new output file will be created, for each section which caused a gap larger than 15 bytes to the previous section. The new file name will get the section’s name appended after a dot.

rawseg Creates a raw binary file for each segment. Segments can be defined in a PhDR block of the linker script. It defaults to text and data segments. The segment names, their base address and length are written into the output file while the binary files get their segment name appended to the original file name. When option -q (keep relocs) has been specified, then additional files containing the relocation offsets are created. The first word in each file defines the number of relocations.

srec19 srec28 srec37 Motorola S-Record format. No symbols. Output format only. Without a linker script, the raw binary will be relocated to base address 0.

vobj-le VOBJ file format, generated by the vasm assembler. VOBJ is a read-only object file format and is designed to support any little- or big-endian architecture with all their specific relocations.

vobj-be

xfile Human68k XFile format, as used on Sharp X68000 computers. Executables only at the moment. Symbol table supports absolute symbols and relocatable symbols from the text, data and bss segment. The format has no differentiation between local and global scope. The internal linker script defines LinkerDB for small data and supports vbcc-style constructor/destructor tables in the data section (__CTOR_LIST__ and __DTOR_LIST__).

2.3 Linker Options

vlink command template:

```
vlink [-dhnqrstvwxMRSX] [-B linkmode] [-b targetname]
[-e entrypoint] [-export-dynamic] [-f flavour] [-fixunnamed]
[-F filename] [-gc-all] [-gc-empty] [-hunkattr secname=value]
[-interp path] [-L library-search-path] [-l library-specifier]
[-static] [-T filename] [-Ttext addr] [-textbaserel]
[-tos-flags/fastload/fastram/private/global/super/readable]
[-tos-textbased] [-u symbol] [-vicelabels filename]
[-V version] [-y symbol] [-P symbol]
input-files...
```

Usually options and input file names can be mixed. Order of options may be important (e.g. when specifying a library with -l or a search path with -L).
The following options are supported:

-Bdynamic
Specifies that linking against dynamic libraries can take place. If a library specifier of the form `-lx` appears on the command line, `ld` searches for a library of the from `libx.so.n.m` (see the `-l` option) according to the search rules in effect. If such a file can not be found a traditional archive is looked for. This options can appear anywhere on the command line and is complementary to -Bstatic.

-Bstatic
The counterpart of -Bdynamic. This option turns off dynamic linking for all library specifiers until a -Bdynamic is once again given. Any explicitly mentioned shared object encountered on the command line while this option is in effect is flagged as an error.

-Bshareable
Instructs the linker to build a shared object from the object files rather than a normal executable image.

-Bsymbolic
This option causes all symbolic references in the output to be resolved in this link-edit session. The only remaining run-time relocation requirements are base-relative relocations, ie. translation with respect to the load address. Failure to resolve any symbolic reference causes an error to be reported.

-Bforcearchive
Force all members of archives to be loaded, whether or not such members contribute a definition to any plain object files. Useful for making a shared library from an archive of PIC objects without having to unpack the archive.

-b targetname
Specifies target file format for the output file. See also "Supported file formats".

-baseoff offset
Defines section offset for base-relative relocations. The default offset is target-depant (e.g. 0x7ffe for amigaos and 0x8000 for elf32m68k).

-C constructor-type
Defines the type of constructor/destructor function names to scan for. Valid types are:

-gnu GNU style constructors

-vbcc vbcc style constructors: `__INIT[<pri>]<name> / __EXIT..`

-vbccelf vbcc style constructors: `__INIT[<pri>]<name> / __EXIT..`

-clr-adduscore
No longer add a preceding underscore for the symbols of the following objects in the command line.

-clr-deluscore
No longer delete a preceding underscore for the symbols of the following objects in the command line.
-d
-dc
-dp      Force allocation of common symbols, even when producing relocatable output
          (-r option).
-da       Force allocation of address symbols (PowerOpen), even when producing relo-
          catable output (-r option).
-e entrypoint
          Defines the entry point of an executable and may be either a symbol or an
          absolute address. The linker will set the entry point by trying each of the
          following methods in order, stopping when the first succeeds:
          1. -e option
          2. ENTRY() command in a linker script
          3. value of the symbol _start, if defined
          4. start of the first executable code section
          5. address 0
-EB       Presets big-endian mode for reading input and writing output.
-EL       Presets little-endian mode for reading input and writing output.
-export-dynamic
          Put all global symbols of the output file into the dynamic symbol table, making
          them visible for shared objects loaded on demand (e.g. by dlopen()).
-f flavour
          Adds a library-flavour. All flavours are cumulatively appended to each library
          search-path, whenever a library was specified with -l. Example: One search
          path and two flavours will search in:
          1. <lib-path>,
          2. <lib-path>/<flavour1> and
          3. <lib-path>/<flavour1>/<flavour2>
-F filename
          A list of object file names is read from the specified file. Useful, if the number
          of objects exceeds the length of the command line.
-fixunnamed
          All unnamed sections will get a default name according to their section type
          (.text, .data and .bss).
-gc-all    Section garbage collection. Starting from the executable's entry point, deter-
          mine all referenced sections and delete the unreferenced ones.
-gc-empty  Delete all empty sections from an executable, which are not referenced from
          anywhere in the linked input files. Note: Before V1.5d vlink tried to do that
          always, but it didn't work in any case.
-h         Prints a short help text.
-hunkattr secname=value
  Overwrite the memory attributes of all input sections named secname with value. For example allocate the DATA section in Chip-RAM: -hunkattr DATA=2. Extended memory attributes are supported. Only valid for AmigaDOS hunk format and WarpOS EHF.

-interp interpreter-path
  Defines the name of the interpreter, which is usually the dynamic linker for dynamically linked ELF executables. Defaults to /usr/lib/ld.so.1.

-k
  Keeps the original section order as found in the object files from the command line. Otherwise vlink links all code sections first, then all data and finally all bss, even when the first object starts with data. Has no meaning when using a linker script!

-L library-search-path
  Add path to the list of directories to search for libraries specified with the -l option. When a default search path was compiled in (see -v), then it is searched last.

-l library-specifier
  This option specifies a library to be considered for inclusion in the output. If the -Bdynamic option is in effect, a shared library of the form lib<spec>.so.m.n (where m is the major, and n is the minor version number, respectively) is searched for first. The library with the highest version found in the search path is selected. If no shared library is found or the -Bstatic option is in effect, an archive of the form lib<spec>.a is looked for in the library search path. For amigaos/amigaehf file formats, the libraries are called <spec>.lib.

-M[<file name>]
  Produce output about the mapping of sections of the input files and the values assigned to symbols in the output file. When the optional file name is missing output goes to stdout.

-minalign alignment
  Set a minimum alignment (number of bits which have to be zero) for all imported sections. The specified alignment value will only take effect when higher than the section's current alignment. It defaults to 0.

-mrel
  Automatically merge sections, when there are PC-relative references between them.

-mtype
  Merge all sections of the same type (code, data, bss), even when their names or attributes differ.

-multibase
  The default behaviour of vlink is to merge all sections which are accessed base-relative. This guarantees a single small data section, which can be accessed through a base register. If this is not desired - maybe you have several base registers and small data sections - you can disable this behaviour by specifying -multibase.
-N oldname newname
   Rename all input sections named oldname into newname. This setting is valid
   for all the following input files and libraries on the command line and can be
   disabled with -N oldname oldname. Multiple -N options are allowed.

-n
   No page alignment of sections or segments in the final executable (NMAGIC).

-nostdlib
   Ignore default library search path, if one was compiled in.

-o filename
   Specifies the name of the output file. Defaults to a.out.

-osec
   Output each section as an individual file. The file name given with -o will be
   ignored. Only available for some target formats: rawbin1, rawbin2, amsdos,
   cbmprg.

-osec=basename
   Works like -osec, but each output file name will be preceded by "basename."

-P symbol
   Protect a symbol from stripping. This doesn’t work for all targets!

-q
   Emit relocations, even for absolute executables.

-R format
   Sets the relocation table format. Usually there is no need to change the default
   format defined by the target (-b option). Valid format strings are:
   
   std    standard format with addends in the code
   add    addends are stored in the relocation table
   short  relocation table with short offsets (e.g. 16 bit)

   Note that most targets only support one or two of those formats.

-r
   Produce relocatable object file, suitable for another linker pass.

-rpath library-search-path
   Add a directory to the runtime library search path. This is used when linking an
   ELF executable with shared objects. All -rpath arguments are concatenated
   and passed to the runtime linker, which uses them to locate shared objects at
   runtime.

-S
   Strip all debugger symbols from the output.

-s
   Strip all symbols from the output.

-sc
   Merge all code sections to a single code section (small code).

-sd
   Merge all data and bss sections to a single data-bss section (small data).

-set-adduscore
   Start adding a preceding underscore for the symbols of the following objects in
   the command line.

-set-deluscore
   Start deleting a preceding underscore for the symbols of the following objects
   in the command line.
- **shared**  
  Instructs the linker to build a shared object from the object files rather than a normal executable image.

- **soname name**  
  Sets the "real name" of a shared object or library. For ELF this will create the SONAME tag in the .dynamic section.

- **T script**  
  Specifies a linker script, which defines the absolute locations for every section. The command language should be the same as that used in GNU linker scripts, although does not implement everything yet. Supported commands:
  
  - ASSERT
  - BYTE
  - CONSTRUCTORS
  - ENTRY
  - EXTERN
  - FILL
  - GROUP
  - INPUT
  - LONG
  - OUTPUT_ARCH
  - OUTPUT_FORMAT
  - PROVIDE
  - QUAD
  - SEARCH_DIR
  - SHORT
  - SQUAD
  - VBCC_CONSTRUCTORS
  - VBCC_CONSTRUCTORS_ELFF

Supported functions:
  
  - ADDR
  - ALIGN
  - KEEP
  - LOADADDR
  - MAX
  - MIN
  - SIZEOF
  - SIZEOF_HEADERS
  - SORT

You find the full documentation for GNU linker scripts here: Linker Scripts ([https://sourceware.org/binutils/docs/ld/Scripts.html#Scripts](https://sourceware.org/binutils/docs/ld/Scripts.html#Scripts))
-T text addr
  Set the base address of the first section. It can be overridden by a linker script.

-t
  Trace the linker’s file accesses.

-textbaserel
  Allow base-relative access on code sections. Otherwise the linker will display a
  warning.

-tos-flags value
  Set the 32 bit flags field of the Atari TOS header to value. All -tos options
  are only valid for the targets ataritos and aoutmint.

-tos-fastload
  Sets the fastload bit (0) in the TOS header.

-tos-fastram
  Sets the fastload bit (1) in the TOS header.

-tos-fastalloc
  Sets the fastload bit (2) in the TOS header.

-tos-private
  Sets the flags in the TOS header to mark memory space as private.

-tos-global
  Sets the flags in the TOS header to mark memory space as global (read/write
  by any process).

-tos-super
  Sets the flags in the TOS header to mark memory space as read-writeable by
  processes in supervisor mode only.

-tos-readable
  Sets the flags in the TOS header to mark memory space as read-only for other
  processes.

-tos-textbased
  Writes text-based (offset to program start) DRI symbols to a TOS executable,
  like Devpac. Otherwise symbol offsets are based on the section they are defined
  in.

-T text addr
  Sets the start address of the first section, as long as it is not overwritten by a
  linker script.

-u symbol
  Marks symbol as undefined in the first section which was found on the command
  line. This might trigger linking of additional modules from standard libraries.
  This is equivalent to the linker script command EXTERN.

-V version
  Minimum major version of shared object to be linked behind this option.

-v
  Prints vlink version string, default library search path and implemented target
  file formats.
-vicelabels filename
   Generates a label address mapping file to the VICE debugger.
-w                  Suppress all warning messages.
-X                  Discard local symbols in the input files that start with the letters 'L' or 'l', or with a dot.
-x                  Discard all local symbols in the input files.
-y symbol           Trace the manipulations inflicted on symbol.
-Z                  Do not delete trailing zero-bytes at the end of a section in executable output files. Usually the uninitialized part of a section is determined by the difference between the section’s real size and file size (for those file formats which support it).

2.4 Known Problems
- Neither shared objects nor dynamically linked executables can be generated for .a.out format.
- The following options are not really supported: -S, -X, -Bsymbolic
- Source level debugging support is missing for some formats.
- Many linker script commands are still missing.
- Default linker scripts are mostly missing, so you need to provide your own script when using the -T option.
- PHDR support for ELF is not perfect.

2.5 Credits
All those who wrote parts of the vlink distribution, made suggestions, answered my questions, tested vlink, reported errors or were otherwise involved in the development of vlink (in ascending alphabetical order, probably not complete):

57. %s: Merging a code section with name "__MERGED"
58. Relative references between %s section "%s" and %s section "%s" (%s) force a combination of the two
59. Can’t define %s as ctors/dtors label. Symbol already exists.
60. %s: ELF section header type %d in %s is not needed in shared objects
61. %s: Endianess differs from previous objects
62. Target file format doesn’t support relocatable objects
63. Predefined limits of destination memory region %s for section %s were exceeded (0x%llx)
64. Section %s(%s) was not recognized by target linker script
65. %s line %d: Unknown keyword <%%s> ignored
66. %s line %d: ‘%c’ expected
67. %s line %d: Absolute number expected
68. %s line %d: Keyword <%%s> expected
69. %s line %d: GNU command <%%s> ignored
70. %s line %d: Unknown memory region <\%s>
71. %s line %d: Multiple constructor types in output file
72. %s line %d: Syntax error
73. %s line %d: Assertion failed: %s
74. %s line %d: SECTIONS block defined twice
75. %s line %d: Segment %s is closed and can’t be reused
76. %s line %d: Address overrides specified %cMA memory region
77. %s line %d: Segment %s must include both, FILEHDR and PHDR
78. %s line %d: Missing argument
79. %s line %d: Undefined section: <\%s>
80. %s line %d: Section %s was assigned to more than one PT_LOAD segment
81. Multiple use of section <\%s> in linker script
82. Intermediate uninitialized sections in ELF segment <\%s> (first=<\%s>, last=<\%s>) will be turned into initialized
83. Section <\%s> (0x%llx-0x%llx) conflicts with ELF segment <\%s> (currently: 0x%llx-0x%llx)
84. %s: QMAGIC is deprecated and will no longer be supported
85. %s: a.out %s table has illegal offset or size in %s
86. %s: a.out %s table size in <\%s> is not a multiple of %d
87. %s: a.out symbol name has illegal offset %ld in %s
88. %s: a.out symbol %s has illegal binding type %d in %s
89. %s: a.out relocations without an appropriate section in %s
90. %s: illegal a.out relocation in section %s at offset 0x%08lx: <pcrel=%d len=%d ext=%d brel=%d jmptab=%d rel=%d copy=%d>
91. %s: illegal a.out external reference to symbol %s in %s, which is no external symbol
92. %s: illegal nlist type %lu in a.out relocation in section %s of %s at offset 0x%08lx
93. Target %s: Common symbol %s is unreferenced and will disappear
94. Target file format doesn’t support executable files
95. %s: a.out relocation <pcrel=%d len=%d ext=%d brel=%d jmptab=%d rel=%d copy=%d> is treated as a normal relocation in section %s of %s at offset 0x%08lx
96. %s: size %d for a.out symbol %s in %s was ignored
97. Target %s: %s section must not be absent for a valid executable file", EF_FATAL,
98. Target %s: Section %s is overlapping %s
99. %s line %d: Illegal PHDR type: <\%s>
100. %s line %d: <\%s> behind SECTIONS ignored
101. %s line %d: Address symbol '.' invalid outside SECTIONS block
102. %s line %d: Reference to non-absolute symbol <\%s> outside SECTIONS", EF_ERROR,
103. %s line %d: Division by zero
104. %s line %d: Unknown symbol or function: <\%s>
105. %s line %d: No function-calls allowed here
106. %s line %d: Symbol <\%s> is not yet assigned
107. %s line %d: Command <\%s> not allowed outside SECTIONS block
108. %s line %d: Address symbol '.' cannot be provided
109. %s line %d: Symbol <\%s> already defined
110. %s line %d: Only absolute expressions may be assigned outside SECTIONS block
111. %s line %d: Unknown PHDR: <\%s>
112. %s (%s+0x%lx): Cannot resolve reference to %s, because section %s was not recognized by the linker script
113. %s (%s): %d bits per byte are not supported
114. %s (%s): %d bytes per target-address are not supported
115. %s (%s): Relocation type %d (offset=%lld, bit-offset=%d bit-size=%d mask=0x%llx refering to symbol <\%s> (type %d) is not supported
116. %s (%s): Symbol type %d for <\%s> in section %s is not supported
117. %s (%s+0x%lx): Cannot resolve %s reference to %s, because host section %s is invalid
118. %s: Malformatted ELF %s section in %s
119. %s: Ignoring junk at end of ELF %s section in %s
120. %s (%s+0x%lx): Relocation based on missing %s section
121. %s (%s+0x%lx): Base-relative reference to code section
122. Relocation table format not supported by selected output format - reverting to %s's standard
123. Unknown relocation table format '%s' ignored
124. Target %s: multiple small-data sections not allowed
125. .ctors/.dtors spread over multiple sections
126. Dynamic symbol reference not supported by target %s
127. %s: ELF symbol name has illegal offset 0x%lx in %s
128. %s: Unknown endianess defaults to %s-endian. Consider using -EB/-EL
129. Resetting the same attribute for section %s
130. Bad assignment after option '%s'
131. Need a valid symbolic entry when using -gc-all
132. Executable code section in first object required when using -gc-all
133. Unsupported absolute relocation (offs=%lld pos=%d siz=%d msk=0x%llx) in resident data section
134. %s (%s+0x%lx): Absolute reference to resident data section (%s)
